Medical Imaging Project

Members of team:

Adriel Arias – 1621983 (soft number), Computer Science, Senior undergraduate

Jose Alvarez – 1587271 (soft number), Computer Science, Senior undergraduate

Introduction:

The purpose of our project is to be able simulate data acquisition. By analyzing this data and applying certain algorithms to them like Fourier transforms we should be able to more accurately depict the data in a manner that is user friendly.

Aims:

1. To develop a user friendly, yet visually pleasing, GUI.
2. Generate Phantoms for testing and validation.
3. To apply Fourier transforms and evaluate what types of images are created from Cartesian and Radial trajectories.
4. Study the effects or the reconstructed images depending on the acquisition parameters.
5. Compare the signal intensities of the input image and the final result

Methods

To develop our GUI (1) we used PyQT5. This allowed us to add the option for the user to select what acquisition trajectory they wanted to use. Through the GUI, the user can either choose one of our generated phantoms or input their own image with a "browse" button. Furthermore, the user can see the generated k-space before and after an acquisition trajectory was applied (3), as well as how changing their parameters, with a slider, affects the outcome (4). In order to generate the phantoms, we used Skimage and created the sizes of the objects relative to that of the image with the functions phantom1() and phantom2() (2). We then used the function shiftedDFT() which used numpy fft functions to calculate the Fourier Transform of the image and shift it before returning. From this we can output to the GUI how the k-space looks (3). Then, we generate a mask, depending on the user trajectory selection, to multiply with the k-space and output back to the GUI (3). From this we can now generate the original image after it has been modified with the revertDFT() function. Finally, we are able to compare the new signal intensity with the previous signal intensity from the input image. The way

this is done is by capturing the intensities at certain pixels of the image from 0-255 depending on how intense the objects are, similar to a histogram (5)

Results and Discussion:

(Aim 1 and Aim 2) We developed an easy to use GUI that gives the user the option to input their custom image or generate a phantom1/phantom 2 image. The user will also be given the option to choose the phantom size (512x512/1024x1024/2048x2048/4096x4096) and the acquisition trajectory. This will then show the user the selected image as a small preview.

(Aim 5) Once the user presses the run button, the signal intensity of the inputted image will be presented underneath. Similarly, the signal intensity of the resulting image will be displayed at the top right of the application.
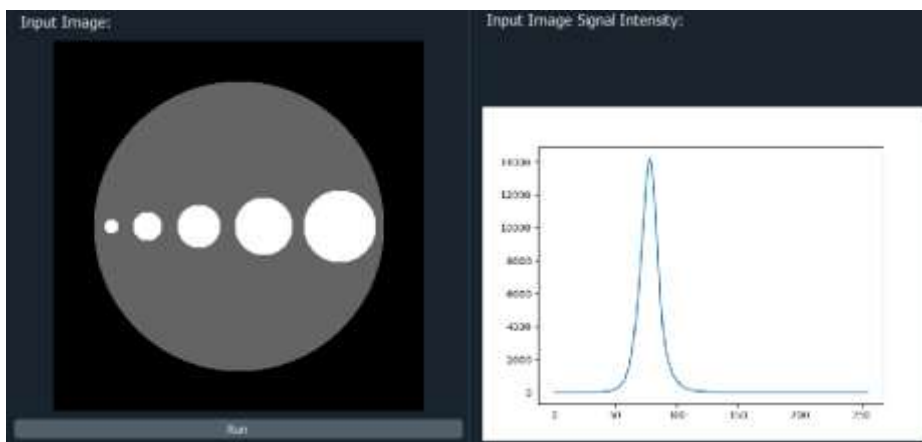

(Aim 3) In our GUI we can also display to the user the k-space generated from the input image and the collected k-space according to the acquisition trajectory they previously set. The image below shows the radial acquisition trajectory being applied with the radius being 50% of the image

This is how the final GUI interface would look to the user after the final image is calculated from the acquisition trajectory:
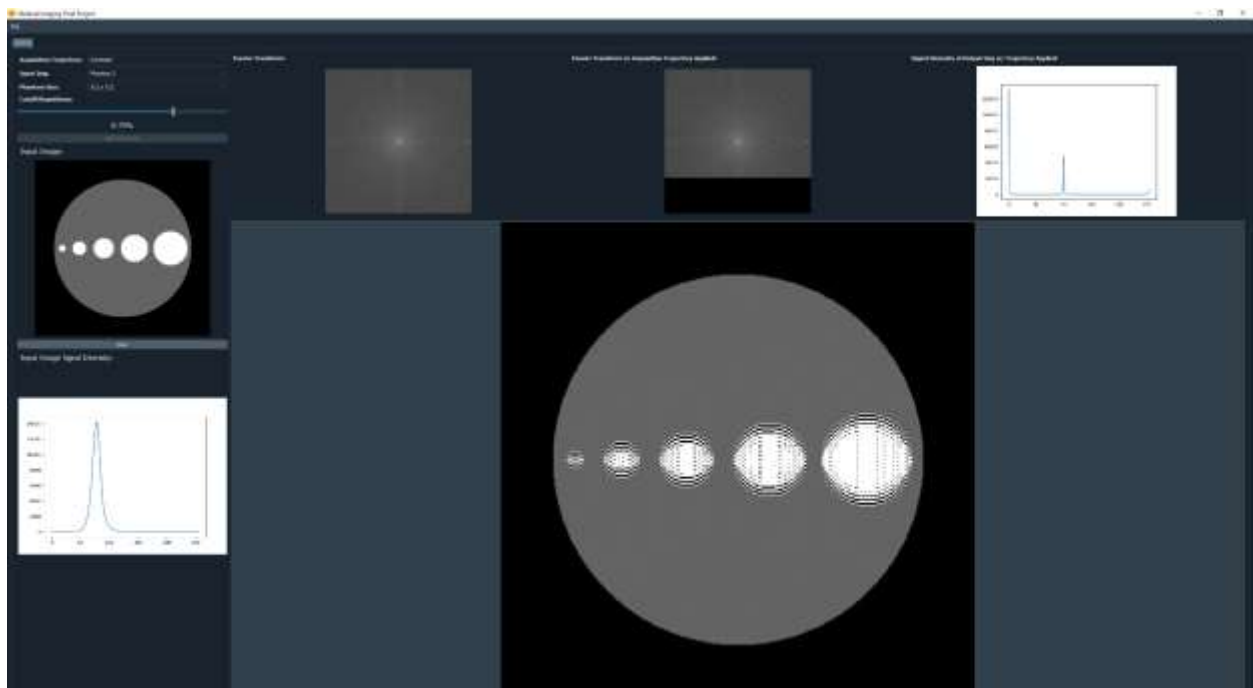

This allows the user to compare the final and original phantom. If one wants to see how changing the acquisition trajectory, one can simply change the slide under "cutoff/repetitions". The images below demonstrate how changing this slider can impact the final result:
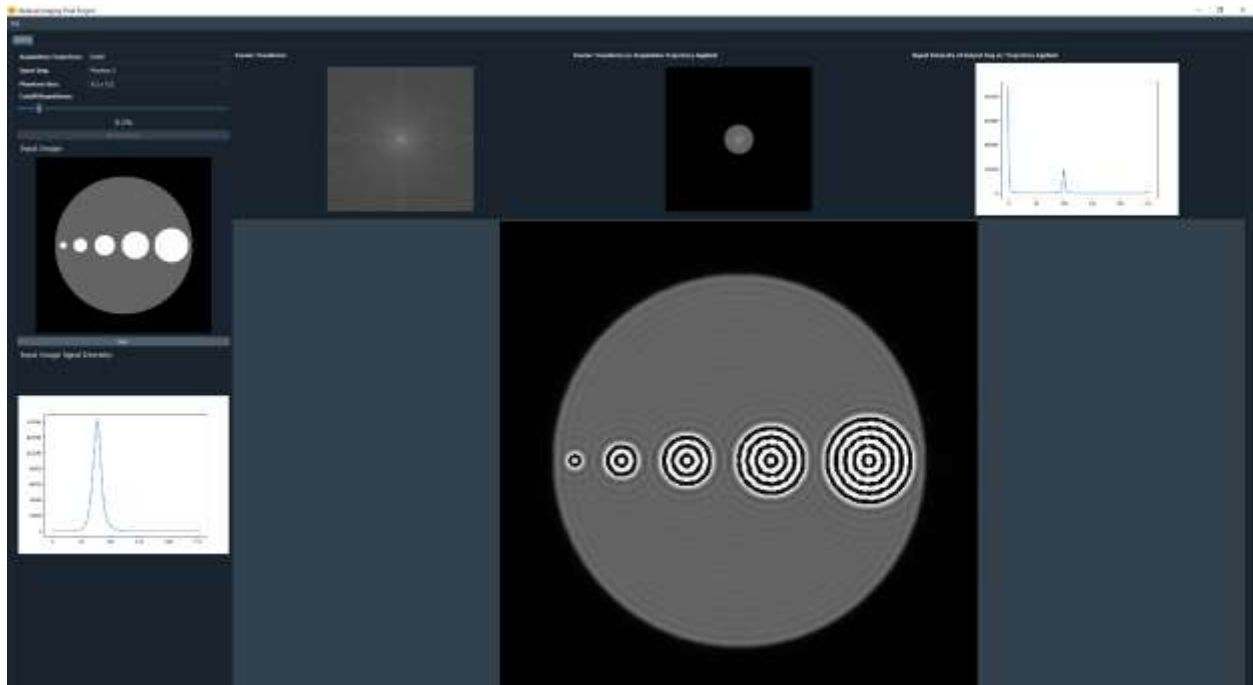

Radial Acquisition Trajectory at 10%
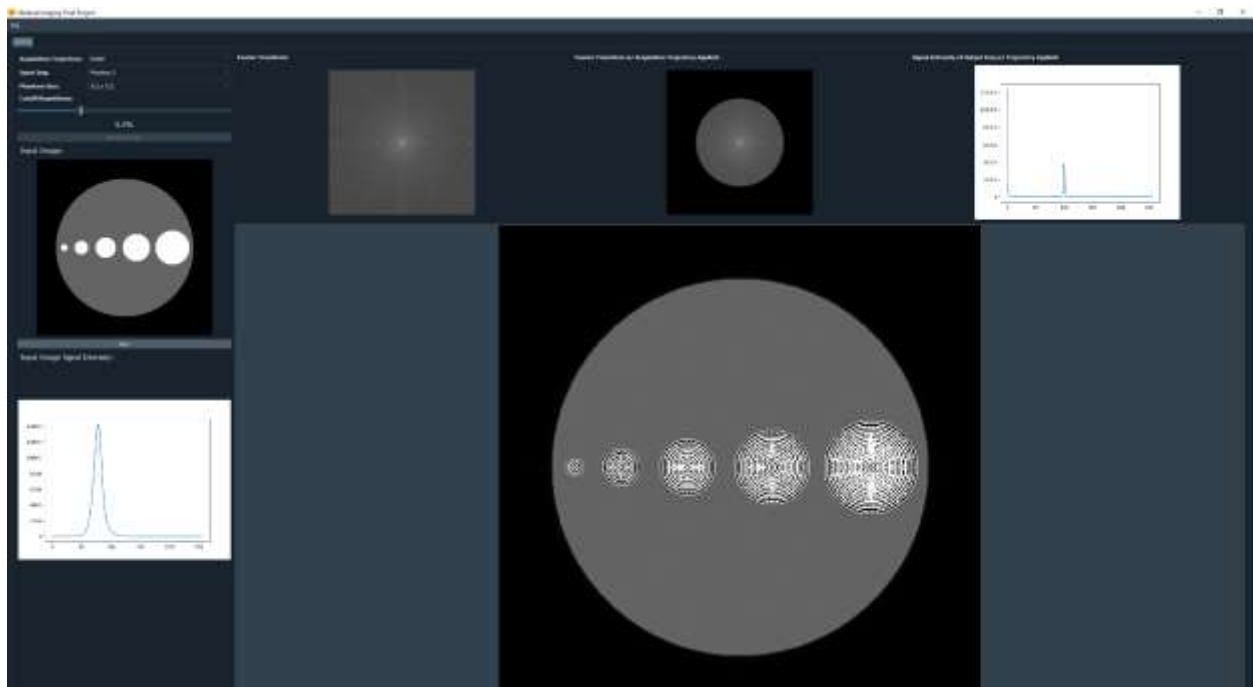

Radial Acquisition Trajectory at 30%
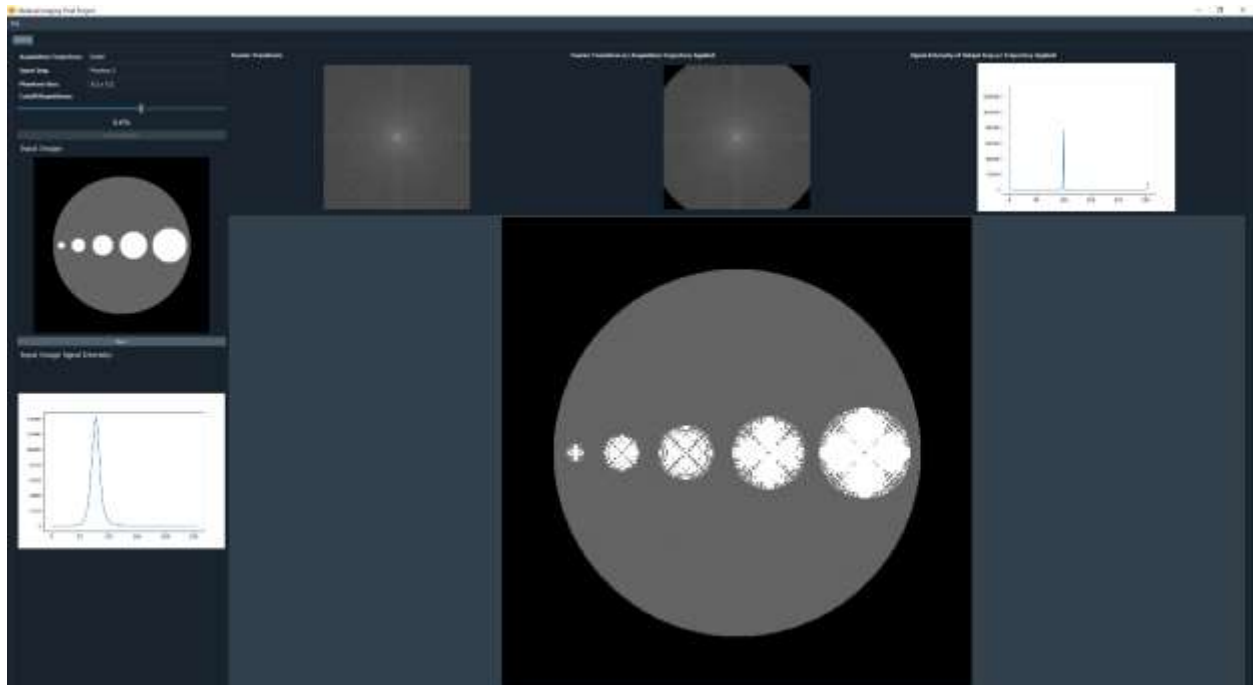

Radial Acquisition Trajectory at 60%

The same can be done for Cartesian!

Cartesian Acquisition Trajectory at 70%

<u>Specifics:</u>

8. Using the test/validation phantom investigate the effect of changing acquisition parameters. In all cases the "ground truth" is your original phantom! You will compare the images generated by your code relative to this phantom! Use the different tools in section 5 to investigate how your scanner works. Compare the image and the validation phantom for different acquisition parameters:
   - How the edges of the rectangular structure the first phantom are appear in the image? Any improvements?
   - In the phantom with the circular structures, what is the effect on them?
   - What is the overall image impression?
   - What parameters give you the best possible image?
   - Add a time parameter and (e.g. this will be the duration of data acquisition per horizontal line for the Cartesian acquisition, and per radial line for the radial acquisition) and investigate how "the longer the acquisition time the better the collected images"

<u>Answers:</u>

- There seems to be no improvement from collecting certain k-spaces.
- The phantom with the circular structures seems to improve the longer the acquisition time is
- The overall image impression is that the parameters depend a lot on the image quality
- The parameters that give the best result are the radial acquisitions with a longer time.
- It seems that the longer the acquisition the better because it allows more data in

Conclusions

We were able to successfully execute all our aims. The user is can choose what trajectory they want with the image of their choice to analyze the reconstructed images. To further analyze the reconstructed images, the user can also change the parameters and see how changing the trajectory affects the final result.

The instructions to run the GUI can be found in the readme.

```python
CODE:
import numpy as np
import cv2
from skimage.draw import circle
from skimage.draw import rectangle
from math import floor
from PIL import Image

class DFT:

    #generates the first phantom image
    def phantom1(self, x, y):
```

```python
        #begins the first image with the size (x,y)
        img = np.zeros((y,x),dtype='uint8')

        rr, cc = circle(y/2,x/2,floor(x*.39))
        img[rr,cc] = 100

        recHeight = floor(y*.58)
        recWidth = floor(x*.12)

        originY = floor((y/2)-(recHeight/2))
        originX = floor((x/2)-(recWidth/2))
        #coordinate of the origin
        start = (originY, originX)
        extent = (floor(y*.58),floor(x*.12))
        rr, cc = rectangle(start, extent=extent,shape=img.shape)

        img[rr,cc] = 255

        # cv2.imwrite('phantom1.jpg',img)
        # cv2.imread('phantom1.jpg')
        return img

    #generates the second phantom image
    def phantom2(self, x, y):

        img = np.zeros((y,x),dtype='uint8')
